Infection with *Marteilia sydneyi*

Also known as Marteiliosis and QX disease

From *Aquatic animal diseases significant to Australia: identification field guide*, 5th edition

Figure 1 Sydney rock oysters (*Saccostrea glomerata*) infected with *Marteilia sydneyi*

![Image of infected oysters](image_url)

Note: Shrunken, pale yellowish, watery digestive gland typical of oyster infected with QX disease (left). Normal digestive gland of oyster is darker (right).

Source: B Diggles

**Signs of disease**

Important: Animals with this disease may show one or more of these signs, but the pathogen may still be present in the absence of any signs.

Disease signs at the farm, tank or pond level are:

- reduced growth rate
- gaping shells
- high cumulative mortalities of up to 100%.

Gross pathological signs are:

- shrunken, watery body
- generally poor condition
- death often within 60 days of infection
- colourless and translucent tissue because the gonad is completely resorbed
- digestive gland (usually a deep green or brown colour) becomes pale yellow or brown.
Microscopic pathological signs are:

- focal haemocytic inflammation of the gills
- hyperplasia of the connective tissue and gill epithelium, with fusion of gill filaments
- massive infection of the digestive gland tubule epithelium with sporogenic stages.

**Disease agent**

*Marteiliosis* (also known as QX disease) is caused by infection with *Marteilia sydneyi*. This protozoan parasite (order Paramyxa, class Ascetosporea) infects the digestive system of Sydney rock oysters and mud dwelling polychaete worms. Other closely related species of *Marteilia* may cause similar diseases, including *M. pararefringens* in oysters and mussels, *M. cochillia* in cockles, *M. octospora* in razor shells, and *M. refringens* in oysters, mussels, cockles and clams.

**Host range**

*Marteilia sydneyi* has an indirect life cycle. Mud-dwelling polychaetes are one known intermediate host, but there may be others.

**Presence in Australia**

Infection with *M. sydneyi* is responsible for losses in the Sydney rock oyster industry on the east coast of Australia. The parasite and disease are present in Queensland and New South Wales. A related species of *Marteilia* has been detected in apparently healthy Australian flat oysters (*Ostrea angasi*) in New South Wales. A *Marteilia* sp. (probably *M. sydneyi*) was officially reported in 1994, associated with disease in the coral rock oyster (*Saccostrea cucullata*) in Western Australia.

**Map 1 Presence of *Marteilia sydneyi*, by jurisdiction**
Infection with *Marteilia sydneyi*

**Epidemiology**

- The presence of the *Marteilia sydneyi* in eastern Australian estuaries is not always accompanied by QX disease. Most of the estuaries that are free of QX disease have less anthropogenic disturbance in the catchment.
- Oysters may be subjected to infection for a period of as little as 2 weeks per year.
- Outbreaks of disease occur in summer and autumn. Warm temperatures favour parasite development, leading to greatest mortality at the end of summer.
- Onset of the disease is often associated with immunosuppression of oysters due to stressors such as flooding or low salinity, high water temperature and excessive sedimentation.
- Transmission is horizontal. The pathogen passes from the environment into the epithelium of the palps and gills, where it proliferates without forming spores. In advanced infections, spores are formed in the digestive gland epithelium.
- Oysters that carry low levels of *M. sydneyi* infections can shed the parasite and make a full recovery.
- The life cycle of *M. sydneyi* is indirect but not fully understood. Intermediate hosts are required to complete the life cycle. Benthic mud-dwelling polychaetes such as *Nephtys australiensis* are one of possibly several intermediate hosts.
- Increased virulence of *M. sydneyi* in degraded estuaries compared to historical times may be due to a combination of several factors. These include increased immunosuppression of the host due to declining water quality together with increased abundance of polychaete intermediate hosts that are favoured by sedimentation, eutrophication and other anthropogenic changes derived from catchment development.

**Differential diagnosis**

The list of similar diseases in the next section refers only to the diseases covered by this field guide. Gross pathological signs may also be representative of diseases not included in this guide. Do not rely on gross signs to provide a definitive diagnosis. Use them as a tool to help identify the listed diseases that most closely account for the observed signs.

**Similar diseases**

Infection with *Marteilia refringens*.

The clinical signs of infection with *M. sydneyi* are almost identical to those of infection with other *Ascetosporea*. These include high mortalities associated with colourless and translucent tissue, poor condition, pale digestive gland and a shrunken body. Any presumptive diagnosis requires further laboratory examination. Light microscopy can contribute diagnostic information, but further laboratory examination and molecular diagnostic techniques are required for a definitive diagnosis.
**Sample collection**

Only trained personnel should collect samples. Using only gross pathological signs to differentiate between diseases is not reliable, and some aquatic animal disease agents pose a risk to humans. If you are not appropriately trained, phone your state or territory hotline number and report your observations. If you have to collect samples, the agency taking your call will advise you on the appropriate course of action. Local or district fisheries or veterinary authorities may also advise on sampling.

**Emergency disease hotline**

See something you think is this disease? Report it. Even if you’re not sure.

Call the Emergency Animal Disease Watch Hotline on **1800 675 888**. They will refer you to the right state or territory agency.
